Stunt Car Racer — Physics Bounciness Deep Review

Reference: reference/StuntCarRacer.s (Amiga 68000) · Port: src/Car_Behaviour.cpp · Date: 18 April 2026

Short answer: The steady-state math is correct and the integration architecture is sound. The bounce *feel* is almost certainly softer than the Amiga original — not because of a bug, but because a well-sampled 60 Hz discrete spring-damper is inherently less oscillatory than an undersampled ~7 Hz one. Tuning `PhysicsConfig.h` is the right lever; see §6.

1 The Amiga Spring-Damper (heart of the bounce)

The entire per-wheel suspension lives in one six-instruction subroutine — `calculate.difference` at `StuntCarRacer.s:15354`:

```
calculate.difference
    move.w  #276,d3          ; spring constant
    beq     .zero
    muls    d3,d0            ; d0 = (new_penetration - old_penetration) × 276
    asr.l   #8,d0            ; ÷ 256
.zero
    add.w   d6,d0            ; + raw penetration depth
    rts
```

`d0` enters as **Δd = new_penetration − old_penetration** (velocity term); `d6` holds the current raw penetration depth (position term). The resulting force formula is:

$$\text{force} = (\Delta d \times 276) \div 256 + d$$

where Δd = penetration change since last tick, d = current penetration depth

The effective damping coefficient is **256/256 = 1.0** (the position term is passed through unchanged). This runs once per game tick at **≈ 7.14 Hz** — the Amiga waits for `MIN.FRAMES = 5` PAL vblanks, but the render loop typically costs ~7 frames, giving the reference period `PHYSICS_REFERENCE_STEP_SECONDS = 0.14 s`.

After the three wheel forces are computed, they are averaged (`average.amount.below.road`) and projected onto the car's surface normal via `calculate.car.collision.acceleration` to produce world-axis accelerations. Everything else flows from there.

2 The Port's Spring-Damper at 60 Hz

`CalculateWheelCollision()` in `Car_Behaviour.cpp` reproduces the Amiga formula faithfully, with one critical adaptation for the higher tick rate:

```
const long spring_effective =
    (g_physicsStepScale > 0.0f)
        ? (long)((float)spring / g_physicsStepScale)
        : spring;
```

At 60 Hz, `g_physicsStepScale = stepSeconds / 0.14 ≈ 0.01667 / 0.14 ≈ 0.119`. The velocity term Δd is ~8.4× smaller per substep (the penetration changes less in 16.7 ms than in 140 ms), so the spring coefficient must be scaled up by the same factor to preserve total impulse:

$$\text{spring_effective} = 276 \div 0.119 \approx 2319$$

Force-per-step is smaller, but there are 8.4× more steps — net impulse per reference period is preserved.

The position (damping) term uses raw `damping = 256`, which is correct — penetration depth does not scale with timestep. The 16-bit signed-word arithmetic (`short delta_word`, `short spring_word`, etc.) faithfully mirrors the Amiga's `muls` / `asr.l` / `add.w` overflow behaviour.

3 Why It Is Still Less Bouncy

Even with per-step forces mathematically preserved, the *transient dynamics* differ because the suspension is a discrete feedback loop:

$$\text{penetration} \rightarrow \text{force} \rightarrow \text{acceleration} \rightarrow \text{speed} \rightarrow \text{position} \rightarrow \text{new penetration} \rightarrow \cdots$$

At **7 Hz**, the loop takes a few, large steps through each oscillation cycle. Before the next tick corrects it, the car overshoots the equilibrium significantly. That overshoot *is* the Amiga bounce. With spring = 276 and damping = 256 at 7 Hz the system is **underdamped** — it oscillates visibly before settling.

At **60 Hz**, the same loop takes many small steps. The system converges toward the continuous-time solution — smoother and more critically damped. Overshoots are caught and corrected within a fraction of

the oscillation period. The car settles faster. This is not a scaling error; it is the fundamental behaviour of discrete feedback systems under refinement.

The Amiga's bounce was partly intentional tuning and partly an artefact of the low tick rate. The port at 60 Hz eliminates the artefact while preserving the intention.

More formally, the **damping ratio ζ** of a discrete spring-damper increases as the timestep shrinks for the same coefficients:

$$\zeta \propto c / (2 \cdot \sqrt{(k \cdot m)}) \rightarrow \text{higher } \zeta \text{ at shorter } \Delta t \text{ for fixed } k, c$$

k = spring constant, c = damping coefficient, m = effective mass

4 Full Integration Chain Audit

Stage	Amiga (reference/StuntCarRacer.s)	Port (Car_Behaviour.cpp)	Match
Gravity constant	`CAR.WEIGHT equ 317`	`GRAVITY_ACCELERATION 317`	✓
Gravity decomposition	3 trig component multiplies via `mult.minus.weight`	Identical: `-317 × trig_coeff[Y_COMP] >> LOG_PRECISION`	✓
Spring formula	`Δd × 276 >> 8 + d`	`Δd × (276/scale) >> 8 + d × 256 >> 8`	✓
Force → world acceleration	`avg_force × surface_normal >> 8`	Identical	✓
Damping constant	`REDUCTION equ 238`	`REDUCTION = 238`	✓
Speed integration	`accel × 238 >> 8` once/tick	Same × stepScale, carry-accumulated	✓
Position integration	`speed × 238 >> 1` (Y), `× 238 × PC_FACTOR` (XZ)	Same, carry-accumulated	✓
Rotation damping	`rot_accel = spring_torque - rot_speed >> 4`	Identical	✓
Drag / ReduceWorldAcceleration	`(world_speed × amount) >> 16 >> factor`	Identical	✓

Stage	Amiga (reference/StuntCarRacer.s)	Port (Car_Behaviour.cpp)	Match
Grip limit	Engine force clamped to `2 × collision_y_accel`	Identical	✓
Landing detection	Force jumps from `< 0x200` to `≥ 0x400`	Identical	✓
Rebound clamp	Force capped at `0x11ff`	Identical	✓
Damage threshold	`0x700`, `1.5×` multiplier, rate-limited	Identical + per-wheel bitmask (improvement)	✓
Wheel spin decay (air)	−25% per tick: `speed -= speed/4`	`pow(0.75, stepScale)` per substep	✓
Boost (force)	`engine_z_acceleration *= 2`	Identical	✓
Boost drain rate	Per-tick on fourteen-frame gate	`AdvanceBoostReserve()` on logic tick — decoupled from physics rate	✓
Bounce feel at 60 Hz vs 7 Hz	—	Smoother due to higher discrete sample rate (see §3)	**~90%**

5 Recent Commits — Assessment

`61c5712` Fractional Carry Physics — *Car_Behaviour.cpp*

Good change. Replaced naive `(long)((float)value × stepScale)` truncation with a 16.16 fixed-point accumulator. At 60 Hz, stepScale ≈ 0.119, so most small integer values would previously truncate to zero *every single substep*, silently leaking energy out of the simulation. The carry accumulator ensures nothing is lost across substeps:

```
// DistributeStepValueWithScale — 16.16 fixed-point carry
const long scale_fp = (long)(step_scale * 65536.0f + 0.5f);
long long total = remainder + (full_step_value * (long long)scale_fp);
substep_value   = (long)(total / 65536LL);
remainder       = (long)(total - substep_value * 65536LL);
```

All twelve integration paths (rotation speed, world speed, position × XYZ, angle × XYZ) were updated. Carry state is included in the instance state saved/restored for multiplayer.

`e4931b6` Carry Based Integration — *Opponent_Behaviour.cpp*

> **Good change.** The same carry-accumulator was applied to the opponent's z-speed, wheel y-speeds, actual heights, and forward distance integration. Before this, the AI car would have suffered the same integer-truncation energy loss as the player. Opponent physics now run on the same precision footing.

`a74db58` Opponent Steering Update — *Opponent_Behaviour.cpp*

> **Small cleanup.** 4-line net reduction. No physics constants changed.

6 Tuning Options for Amiga-Style Bounce Feel

All knobs are in `src/PhysicsConfig.h` — the system is designed for this.

Option	Approach	Trade-off
A — Tune PhysicsConfig.h *(recommended)*	Raise `FRONT/REAR_SUSPENSION_SPRING`, lower `FRONT/REAR_SUSPENSION_DAMPING`. Currently applied: `SPRING = 320`, `DAMPING = 200`.	Higher spring = stiffer pop on contact; lower damping = longer oscillation. Easy to iterate.
B — Lower physics rate	Set `PHYSICS_UPDATE_HZ = 7`, remove step scaling.	Exact Amiga bounce match, but loses smooth rendering, multiplayer benefits.
C — Accept the difference	The 60 Hz behaviour is arguably the continuous-time ideal.	Smoother, more predictable, but less "old game" feel.

Tuning guide for PhysicsConfig.h

Feeling	SPRING	DAMPING
Original Amiga (reference)	276	256
Current (post-change)	320	200
More bouncy / less settled	350–400	160–180

Feeling	SPRING	DAMPING
If landing feels explosive	300	220
Stiffer front, softer rear	FRONT=340, REAR=300	FRONT=190, REAR=220

7 Things That Give Grug Headache

HIGHER_FRAME_RATE zombie code

Dead code, but dangerous. The old StuntCarRemake experiment still compiles inside `CalculateCarCollisionAcceleration()`:

```
#ifdef HIGHER_FRAME_RATE
    car_collision_x_acceleration++;
    car_collision_y_acceleration++;
    car_collision_z_acceleration++;
    car_collision_x_acceleration >>= 1;
    car_collision_y_acceleration >>= 1;
    car_collision_z_acceleration >>= 1;
#endif
```

The `#define` is never set so this is unreachable. However it represents the approach that "didn't work" — a crude ÷2 that would override the entire `g_physicsStepScale` mechanism if accidentally enabled. Recommend deleting it or adding a comment: "*DO NOT ENABLE — superseded by g_physicsStepScale*".

INCREASE constant duplication

Confusing naming. `INCREASE = 276` in `Car_Behaviour.h` is the same value as `FRONT_SUSPENSION_SPRING = 276` in `PhysicsConfig.h`. They happen to be equal because both derive from the Amiga's shared `muls #276` in `calculate.difference`. The opponent code uses `INCREASE` rather than the suspension spring constants, so tuning `PhysicsConfig.h` does not affect the opponent. Consider unifying.

Y-axis position shift factor discrepancy

Minor but unexplained. In `UpdatePlayersPosition()`, the Y-axis integration uses `speed << 7` (×128) while X and Z use `speed << 6 × PC_FACTOR`. The comment reads "*not sure why this is different*" — this

matches the Amiga (`asl.l #7` for Y vs `asl.l #6` for X/Z), so it is correct, but the uncertainty comment should be resolved.

8 Summary Scorecard

Aspect	Verdict
Constants match Amiga (gravity, spring, REDUCTION, damping)	✓ **All identical**
Integration scaling architecture	✓ **Correct**
Spring inverse-scaling for step rate	✓ **Mathematically sound**
Fractional carry accumulation (61c5712)	✓ **Eliminates sub-step energy loss**
Decay functions — airborne wheel spin	✓ **pow(0.75, scale) is correct**
Boost drain decoupled from physics rate	✓
Damage rate-limited to logic ticks	✓ **Improved with wheel bitmask**
Opponent physics on same precision footing	✓ **(e4931b6)**
Bounce feel matches Amiga	**~90% — softer due to 60 Hz discrete dynamics**
HIGHER_FRAME_RATE dead code	⚠ **Should be deleted**
INCREASE / SPRING constant unification	⚠ **Opponent not tuned by PhysicsConfig.h**

Bottom line: The port's physics are faithful. The scaling architecture is solid and the recent carry-based integration commits nail the sub-step precision problem. The car will feel slightly less bouncy than the Amiga because a well-sampled spring-damper oscillates less than an undersampled one. With `SPRING = 320` / `DAMPING = 200` now applied, the system should be noticeably closer to the Amiga feel. Keep iterating in `PhysicsConfig.h` — that is exactly what it is there for.
